Relational operators test the mathematical relationship between two operands and return a Boolean flag (True or False). This system maps value conditions using standard comparisons:

- >= (Greater than or equal to) & <= (Less than or equal to)
- >(Greater than) & < (Less than)
- == (Equal to)

When structural checks require checking multiple conditions simultaneously, Python connects individual expressions using logical operators:

- and: Yields True only if both independent target relational checks evaluate as valid.
- or: Yields True if at least one condition path is verified as matching.
- not: Reverses the Boolean truth value of an input expression.

Conditional processing allows a program to make decisions by executing specific sections of code only when certain conditions are true. In Python, this is achieved using if, elif (else-if), and else statements. The structure operates sequentially from top to bottom. When a conditional statement evaluates to True, its corresponding block of code runs, and the rest of the conditional chain is skipped. The optional else block serves as a catch-all safety net, executing only if all preceding expressions evaluate to False.

Unlike languages that use curly brackets to define code blocks, Python relies strictly on indentation whitespace (standard practice is 4 spaces or a single tab) to define control paths.

I Exercises

- Develop a program that accepts the names, quantities, and prices of three grocery items, calculates the total bill amount, and displays the final bill in a formatted manner.
- Create a program that accepts the total purchase amount and applicable discount percentage, calculates the discount amount and final payable amount, and displays a formatted billing summary.

II Python Code

Write Python code for above exercise on the blank pages attached at the end of practical.

III Required Resources

Sr.	Name of Resource	Major Specification	Qty.	Remarks
1.	Computer System	Any desktop or laptop computer with basic configuration	One computer system for each student	For each student
2.	Software Package	Python 3.x interpreter, Virtual Studio Code, PyCharm IDE, or Google colab		Installed and configured
