The expense tracker repeatedly accepts expense amounts from the user until the user chooses to stop entering values. Each entered expense is added to a running total using an accumulator variable. Accumulation is a programming technique where a variable continuously stores the result of repeated calculations.

The implementation generally includes the following steps.

Initialize the total expense variable.

Accept expense values from the user.

Add each expense to the accumulated total.

Continue accepting entries using a loop.

Display the final monthly expense.

Python provides simple loop structures along with arithmetic operators that make repetitive calculations straightforward. The while loop is particularly useful when the number of iterations is not known in advance, whereas the for loop is suitable when processing a fixed range of values**.**

VI Exercises

- Develop a program that repeatedly accepts daily expense amounts from the user, calculates the total monthly expenditure, and displays the number of expenses recorded.
- Create a program that records expenses under different categories such as Food, Travel, and Shopping, calculates the total expense for each category, and displays a formatted monthly expense summary.

VII Python Code

Write Python code for above exercise on the blank pages attached at the end of practical.

VIII Required Resources

Sr.	Name of Resource	Major Specification	Qty.	Remarks
1.	Computer System	Any desktop or laptop computer with basic configuration	One computer system for each student	For each student
2.	Software Package	Python 3.x interpreter, Virtual Studio Code, PyCharm IDE, or Google colab		Installed and configured
